

# COOL Parser description

Reyhaneh Derafshi  
610396098

## Introduction

This assignment is about constructing an AST using semantic actions of parser generator. Parser takes the sequence of tokens as input from the lexer and it produces a parse tree of the program and also handle some errors.

The root of the tree is of type program and the leaves are non-terminals. We are building our tree using context free grammar.

## Overall layout

```
%{  
C declarations  
%{  
Bison declarations  
%%  
Grammar rules  
%%  
Additional C code
```

- **Bison declarations** : The Bison declarations section contains declarations that define terminal and nonterminal symbols, specify precedence, and so on.

## syntax

- **Precedence declarations** :

The declarations %left and %right ([left and] right associativity) take the place of %token which is used to declare a token type name without associativity/precedence.

e.i : %right ASSIGN

- **grammar rules** :

result: components...

;

exp:        exp '+' exp

says that two groupings of type exp, with a '+' token in between, can be combined into a larger grouping of type exp.

Scattered among the components can be actions that determine the semantics of the rule. An action looks like this:

{C statements}

result:     rule1-components...  
          | rule2-components...  
          ...

The C code in an action can refer to the semantic values of the components matched by the rule with the construct \$n, which stands for the value of the nth component. The semantic value for the grouping being constructed is \$\$

exp:        ...  
          | exp '+' exp  
            { \$\$ = \$1 + \$3; }

## code explanation

```
| CLASS TYPEID '{' error '}' ';' { yyclearin; $$ = NULL; }  
| CLASS error '{' features_list '}' ';' { yyclearin; $$ = NULL; }  
| CLASS error '{' error '}' ';' { yyclearin; $$ = NULL; }
```

## handling errors in class definitions and body

```
features_list : features { $$ = $1; }  
              | { $$ = nil_Features(); }  
features :  
          | error ';' { yyclearin; $$ = NULL; }
```

nonterminal features\_list can be empty,  
but we cannot allow the features nonterminal to call nil\_Features()

formals are comma-separated arguments, i.e. "formal parameters"

```
formals :  
          | { $$ = nil_Formals(); }
```

empty argument list allowed

expressions are the body of the program

```
expr : OBJECTID ASSIGN expr { $$ = assign($1, $3); }  
  
      | '{' one_or_more_expr '}' { $$ = block($2); }
```

block of expression(s)

```
| LET let_expr { $$ = $2; }
```

nested lets

```
| CASE expr OF case_branch_list ESAC { $$ = typcase($2, $4); }
```

Use `case\_branch\_list` nonterminal to handle one or more cases

```
one_or_more_expr : expr ';' { $$ = single_Expressions($1); }
```

```
| one_or_more_expr expr ';' { $$ = append_Expressions($1, single_Expressions($2)); }
```

one or more expressions, separated by a semicolon

this is not the same as comma-separated expressions (e.g. a list of arguments)

```
| error ';' { yyclearin; $$ = NULL; }
```

recover from an expression inside a block

param\_expr : expr

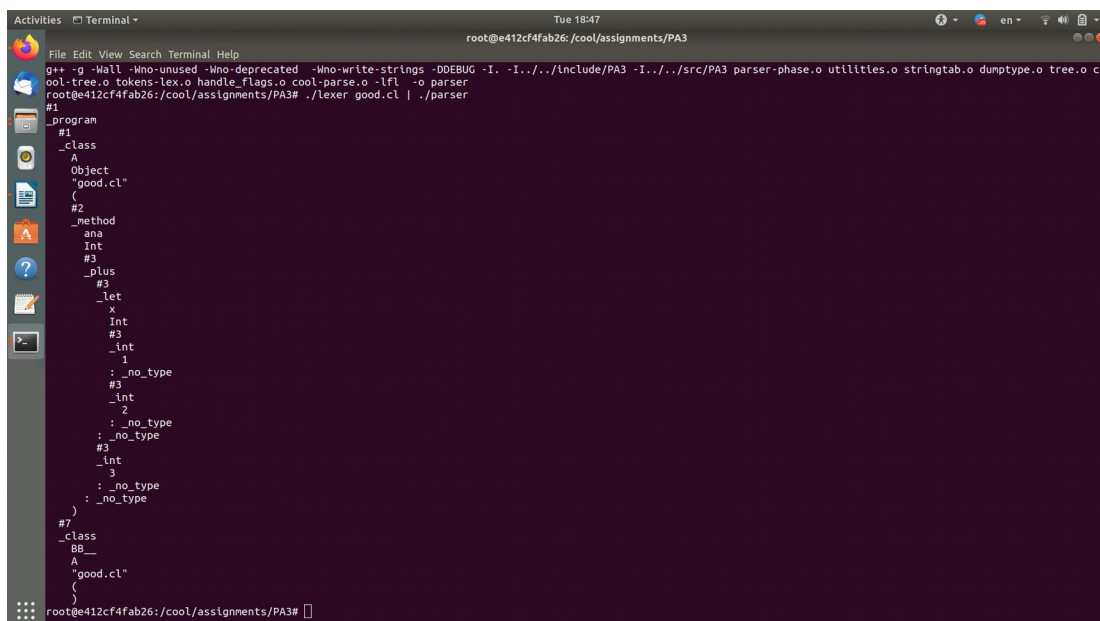

```
| { $$ = nil_Expressions(); }
```

include nil because params are optional

```
case_branch_list : case_branch { $$ = single_Cases($1); }
```

must have at least one case\_branch

output:

```
